## Lecture 2: <br> Maximum Contiguous Subarray Problem

- Reference: Chapter 8 in Programming Pearls, (2nd ed) by Jon Bentley.
- History: 1-D version of a a 2-D pattern recognition problem.
- Clean way to illustrate basic algorithm design
- A $\Theta\left(n^{3}\right)$ brute force algorithm
- $\mathrm{A} \Theta\left(n^{2}\right)$ algorithm that reuses data.
- $\mathrm{A} \Theta(n \log n)$ divide-and-conquer algorithm
- $\mathrm{A} \Theta(n)$ algorithm by revisualizing the problem
- Cost of algorithm will be number of primitive operations, e.g., comparisons and arithmetic operations, that it uses.

## ACME CORP - PROFIT HISTORY

| Year | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Profit M\$ | -3 | 2 | 1 | -4 | 5 | 2 | -1 | 3 | -1 |

Betweeen years 5 and 8 ACME earned $5+2-1+3=9$ Million Dollars
This is the MAXIMUM amount that ACME earned in any contiguous span of years.

Examples:
Between years 1 and 9 ACME earned $-3+2+1-4+5+2-1+3-1=4 \mathbf{M} \$$ and between years 2 and 6
$2+1-4+5+2=6 \mathbf{M} \$$.
The Maximum Contiguous Subarray Problem is to find the span of years in which ACME earned the most, e.g., $(5,8)$.

## FORMAL DEFINITION

Input: An array of reals $A[1 \ldots N]$.
The value of subarray $A[i \ldots j]$ is

$$
V(i, j)=\sum_{x=i}^{j} A(x) .
$$

The Maximum Contiguous subarray problem is to find $i \leq j$ such that

$$
\forall\left(i^{\prime}, j^{\prime}\right), V\left(i^{\prime}, j^{\prime}\right) \leq V(i, j) .
$$

$$
\text { Output: } V(i, j) \text { s.t. } \forall\left(i^{\prime}, j^{\prime}\right), \quad V\left(i^{\prime}, j^{\prime}\right) \leq V(i, j) .
$$

Note: Can modify the problem so it returns indices $(i, j)$.

## $\Theta\left(n^{3}\right)$ Solution: Brute Force

Idea: Calculate the value of $V(i, j)$ for each pair $i \leq j$ and return the maximum value.

VMAX $=A[1]$;
For $i=1$ to $N$

$$
\begin{aligned}
& \text { For } j=i \text { to } N \\
& \quad\{\text { calculate } V(i, j) \\
& V=0 ;
\end{aligned}
$$

For $x=i$ to $j$

$$
V=V+A[x] ;
$$

If $V>$ VMAX then
VMAX $=V$;
\}
Return(VMAX);
$\Theta\left(n^{2}\right)$ solution: Reuse data
Idea: We don't need to calculate each $V(i, j)$ from "scratch" but can exploit the fact that

$$
V(i, j)=\sum_{x=i}^{j} A[x]=V(i, j-1)+A[j] .
$$

$\mathrm{VMAX}=A[1] ;$
For $i=1$ to $N$
$\{V=0 ;$
For $j=i$ to $N$
\{calculate $V(i, j)$
$V=V+A[j]$;
If $V>\mathrm{VMAX}$ then
VMAX $=V$;
\}
Return(VMAX);
$\Theta(n \log n)$ solution: Divide-and-Conquer
Idea: Set $M=\lfloor(N+1) / 2\rfloor$.
Note that the MCS must be one of

- $S_{1}$ : The MCS in $A[1 \ldots M]$,
- $S_{2}$ : The MCS in $A[M+1 \ldots N]$,
- $A$ : The MCS that contains both
$A[M]$ and $A[M+1]$.
Equivalently, $A=A_{1} \cup A_{2}$.

| S_1 |  |  |  |  | S_2 |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| M |  |  |  |  |  | $\mathrm{M}+1$ |

A_1 $=$ MCS on left containing $\mathrm{A}[\mathrm{M}] \quad \mathrm{A} \_2=\mathrm{MCS}$ on right containing $\mathrm{A}[\mathrm{M}+1]$ A=A_1U A_2

## Example:

| 1 | -5 | 4 | 2 | -7 | 3 | 6 | -1 | 2 | -4 | 7 | -10 | 2 | 6 | 1 | -3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| 1 | -5 | 4 | 2 | -7 | 3 | 6 | -1 | 2 | -4 | 7 | -10 | 2 | 6 | 1 | -3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

$S_{1}=[3,6]$ and $S_{2}=[2,6,1]$.
$A_{1}=[3,6,1]$ and $A_{2}=[2,-4,7] ;$
$A=A_{1} \cup A_{2}=[3,6,1,2,-4,7]$
Since $\operatorname{Value}\left(S_{1}\right)=9, \operatorname{Value}\left(S_{2}\right)=9$
and $\operatorname{Value}(A)=13$
the solution to the problem is $A$.

## Finding $A$ : The conquer stage

$A_{1}$ is in the form $A[i \ldots M]$ :
there are only $M$ such sequences, so, $A_{1}$ the maximum valued such one, can be found in $O(M)=$ $O(N)$ time.

Similarly, $A_{2}$ is in the form $A[M+1 \ldots j]$ : there are only $N-M$ such sequences, so, $A_{2}$ the maximum valued such one, can be found in $O(N-M)=O(N)$ time.
$A=A_{1} \cup A_{2}$ can therefore be found in $O(N)$ time.

## The Full Divide-and-Conquer Algorithm

Input: $A[i \ldots j]$ with $i \leq j$.
$\operatorname{MCS}(A, i, j)$

1. If $i==j$ return $(i, j)$
2. Else
3. Find $M C S\left(A, i,\left\lfloor\frac{i+j}{2}\right\rfloor\right)$;
4. Find $\operatorname{MCS}\left(A,\left\lfloor\frac{i+j}{2}\right\rfloor+1, j\right)$;
5. Find MCS that contains

$$
\text { both } A\left[\left[\frac{i+j}{2}\right]\right] \text { and } A\left[\left\lfloor\frac{i+j}{2}\right\rfloor+1\right] ;
$$

6. Return Maximum of the three sequences found

Let $T(N)$ be time needed to run

$$
M S C(A, i, i+N-1) .
$$

Step (1) requires $O$ (1) time.
Steps (3) and (4) each require $T(N / 2)$ time.
Step (5) requires $O(N)$ time.
Step (6) requires $O$ (1) time
Then $T(1)=O(1)$ and for $N>1, T(N)=2 T(N / 2)+O(N)$
$\Rightarrow T(N)=O(N \log N)$.

## Review of Analysis of a D-and-C Algorithm

Note: For more details see CLRS, chapter 3.

To simplify the analysis, we assume that $n$ is a power of 2 .

- In the DC algorithm, Steps 5 and 6 together requires $O(n)$ operations.
- Hence, $T(n) \leq 2 T\left(\frac{n}{2}\right)+c n$. Repeating this recurrence gives

$$
\begin{aligned}
T(n) & \leq 2 T\left(\frac{n}{2}\right)+c n \\
& \leq 2\left[2 T\left(\frac{n}{2^{2}}\right)+c \frac{n}{2}\right]+c n \\
& =2^{2} T\left(\frac{n}{2^{2}}\right)+2 c n \\
& \leq 2^{2}\left[2 T\left(\frac{n}{2^{3}}\right)+c \frac{n}{2^{2}}\right]+2 c n \\
& =2^{3} T\left(\frac{n}{2^{3}}\right)+3 c n \\
& \leq \cdots \\
& =2^{h} T\left(\frac{n}{2^{h}}\right)+h c n
\end{aligned}
$$

Set $h=\log _{2} n$, so that $2^{h}=n$. With this substitution, we have

$$
T(n) \leq n T(1)+\left(\log _{2} n\right) c n=O\left(n \log _{2} n\right)
$$

## The $O(n)$ algorithm

| $i$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $A[i]$ | -2 | 3 | 1 | -3 | 2 | -4 | 3 | -1 | 4 | -2 |  |
| $T(i)$ | 0 | -2 | 1 | 2 | -1 | 1 | -3 | 0 | -1 | 3 | 1 |

Define $T(i)=\Sigma_{x=1}^{i} A[x]$.
Then $V(i, j)=\Sigma_{x=i}^{j} A[x]=T(j)-T(i-1)$.
In particular, for fixed $j$ we can find maximal $V(i, j)$ by finding $i \leq j$ with minimal value of $T(i-1)$.

## Idea behind the algorithm

1. Suppose we've already seen

$$
A[1], A[2], \ldots A[j-1] .
$$

Let $V$ be the value of MCS in $A[1, \ldots j-1]$.
Let $T_{\min }$ be the minimum $T(i)$ value so far.
2. After seeing $A[j]$ calculate

$$
\begin{aligned}
T(j) & =T(j-1)+A[j] \\
V_{\text {possible }} & =T(j)-T_{\min } \\
& =\text { maximum value for a } V(i, j) .
\end{aligned}
$$

3. Update Information:

If $T(j)<T_{\text {min }}$ then
$T_{\min }=T(j) ;$
If $V<V_{\text {possible }}$ then
$V=V_{\text {possible }}$

## The actual $O(n)$ algorithm

$$
\begin{aligned}
& T=A[1] ; V=A[1] \\
& T_{\min }=\min (0, T) ;
\end{aligned}
$$

For $j=2$ to $N$
$\{T=T+A[j]$;
If $T-T_{\min }>V$
then $V=T-T_{\min }$;
If $T<T_{\text {min }}$
then $T_{\text {min }}=T$;
\}
Return( $V$ );

This algorithm implements exactly the ideas on the previous page so it returns the corect answer. Furthermore, since it does only $O(1)$ work for each $A[j]$, it runs in $O(N)$ time.

## Review

In this lecture we saw 4 different algorithms for solving the maximum contiguous subarray problem. They were

- $\mathrm{A} \Theta\left(n^{3}\right)$ brute force algorithm
- A $\Theta\left(n^{2}\right)$ algorithm that reuses data.
- $\mathrm{A} \Theta(n \log n)$ divide-and-conquer algorithm
- A $\Theta(n)$ algorithm by revisualizing the problem

After completing this class you should be capable of finding the first three algorithms by yourself. Deriving those algorithms only require standard algorithmic design tools and approaches.

Tools for deriving the fourth, $O(n)$ time, algorithm can't really be taught in a short class. That derivation requires both cleverness and a mindset that can usually only be developed through practice.
